

Title: Who Created God? : A Philosophical Perspective

It may seem obvious that nothing can exist without being brought into existence. Yet, the question of existence is far more complex than we usually imagine. Religious thinkers are seen as inconsistent because they claim some things are created (such as the universe), while others are not (such as God). In Christianity and Islam, for example, God is defined as uncreated, but we all know that defining something as uncreated doesn't automatically make it so. So instead of starting from the assumption, we should rethink what it actually means for something to be "uncreated". But before going deeper into this discussion, I want to emphasize an important point. Whenever we try to deduce anything, we inevitably rely on certain assumptions that we rarely notice. These assumptions are unavoidable because they are rooted in our experience and the way our mind works.

According to modern philosophy, existence can be defined from many perspectives. However, one commonly repeated formulation, Graham Priest's, is that existence is the realized potential of an entity either to influence its surroundings, to be influenced by them, or both. This definition always reminds me of the Arab philosopher Ibn Sina, who explored similar questions in his work on the soul. He proposes a famous thought experiment. Imagine a person who has lost all of his sensory abilities, hearing, smell, taste, sight and touch, who has no past memories (no language, no name...), and who is suspended in an empty void. Would this person still know that he exists? I think this question clearly reveals the depth of what we are really dealing with.

Ibn Sina's question carries a deep epistemological value, because it examines the existence of an entity from its own perspective. If this inner awareness were absent, we would be left with no basis, at least from that perspective, to affirm the entity's existence. In such a case, the entity's existence would effectively be denied from within, even if the surroundings could still observe and confirm that it is in the act of being.

According to my own philosophy definition, the act of being and existence are not identical. Being can be understood as a mere presence, simply being there. Existence, however, goes further, it involves a relationship of cause and effect with one's surroundings, the capability to affect and to be affected, while still presupposing the act of being. This ontological distinction builds toward a basic principle of existence, one must first know one exists before one can know that others exist. If existence presupposes the act of being, how does something come into being? This leads us directly to the question of creation.

In Quantum field theory, developed after the limitations of classical field theories

became clear, attempts to explain realities in terms of fields. Field is something that has a value at every point in space and time. The field described by this theory is a Quantum field, a field that fills all of space and whose vibrations appear to us as particles and obey Quantum rules, such as Heisenberg uncertainty principle. According to this principle, a system cannot have a perfectly exact position and perfectly zero motion at the same time. As a result, even at its lowest possible energy state, every system must still wiggle slightly. This remaining energy is called zero-point energy, a minimum energy a Quantum system can possess. In other words, even if it tries to remain completely still, it cannot avoid motion entirely. Continuing from this idea, the theory suggests that even empty (vacuum) space is not truly empty. Instead, it is filled with tiny Quantum fluctuations that contain a small amount of energy. This implies that a system with absolutely zero energy is impossible.

But is this zero-point energy created or uncreated? That question is crucial. Discussing energy in a localized versus globalized way is an entirely different matter. Observing how energies(particles) behave across space and time globally, we see them appearing and disappearing seemingly at will, only locally are they strictly conserved. This leads to a profound implication, if energy can spontaneously appear, then matter can too. From this perspective, it is logically valid to suggest that the entire material world could emerge from a metaphysical "nothing". A metaphysical "nothing," by principle, is the absence of any structure, rule, potentiality, distinction, space or time, not merely the absence of matter and energy. It lacks even the framework that would allow something to appear. In this case, if we strictly adhere to the principle "everything has a cause," then God would also fall under this rule and become the effect of some spontaneous appearance. Alternatively, one could argue that the so called metaphysical "nothing" was not truly nothing, because God possesses inherent properties that make Him necessarily existent and independent, not contingent upon anything else.

Or perhaps there are countless possibilities. The question of who or what created God is far too complex, the realities we must consider are far more intricate than our minds can grasp. One could ask, what do we mean by "nothing" in the first place? Does this "absence" include the possibility of thought itself about that "nothing"? If so, then it is not truly "nothing" as we defined it. Does God fall under any law? Is He dependent on Himself for existence? And so on. At this level, language begins to break down, science reaches its limits, philosophy strains under the weight of thought, and mind is left in awe and numbness. What remains is belief.
